42 **Section S1: Data cleaning of vaccine data obtained from National Vaccine Register (NVR)**
43 Vaccination data, the date of vaccination and the brand of vaccine for each dose, was obtained from the National
44 Vaccination Register (NVR), at the Public Health Agency of Sweden. A very short time gap between two doses is
45 likely to represent errors in the data or erroneous repeat registrations of the same dose. Therefore, the second and the
46 following doses were defined as the next vaccination record that is not shorter than the "recommended" minimum
47 time gap from the first dose. The length of the required minimum time gap was decided according to the guidelines
48 for COVID-19 vaccination and depended on the type of vaccine received at the earlier dose. We used 19 days for
49 BNT162b2, and 25 days for AZD1222 and mRNA-1273. The guidelines for BNT162b2 were that the second dose
50 should be 3-7 weeks from the first dose, and it was eventually set to 19 days in order to allow some flexibility
51 around the guidelines. Similarly, for AZD1222 and mRNA-1273, it was recommended to be 4-7 weeks, and was set
52 to be 25 days.

53

54 **Section S2: Data Source of covariates and definition of prior comorbidities and treatments**

55 This study is part of the larger SCIFI-PEARL project with regularly updated data from various National Registers¹.
 56 SCIFI-PEARL retrieved sociodemographic data including country of birth, education, family situation, income and
 57 occupational data from 2018 from the Longitudinal Integrated Database for Health Insurance and Labour Market
 58 Studies (LISA) from Statistics Sweden (SCB). Information on elderly subjects living at special care facilities and/or
 59 receiving home care services came from the National Social Service Register.

60 Additionally, SCIFI-PEARL retrieved a complete specialist care medical history for all individuals from the Swedish
 61 National Patient Register (NPR) from 2015, and a complete drug history for prescription drugs from the National
 62 Prescribed Drug Register (NPDR) from 2019. The five-year prior medical history (using ICD-10 codes) and one-year
 63 prior prescription drugs history (using ATC codes) were used to define the prior comorbidities and treatments.

Prior comorbidities and treatments	Description	ICD-10 or ATC codes	ATC codes
Cardiovascular diseases	Diagnosis from NPR	I05-I09, I20-I51, R001, R011, Q20-Q28	NA
Stroke	Diagnosis from NPR	I60-I62, I630-I635, I638-I639, I64	NA
Hypertension	Diagnosis from NPR, or on medication for hypertension from NPDR	I10-I15	C02-09
Diabetes (type 1 and type 2)	Diagnosis from NPR, or on medication for diabetes from NPDR	E10, E11	A10A, A10B
Obstructive respiratory disease	Diagnosis of COPD/asthma from NPR, or on medication for obstructive airway diseases from NPDR	J44, J45	R03A, R03BA, R03BB, R03C, R03D
Chronic kidney diseases	Diagnosis from NPR	N17-N19	NA
Obesity	Diagnosis from NPR	E66	NA
Autoimmune diseases	Diagnosis from NPR	M05-M14	NA
Dementia	Diagnosis from NPR	F00-F03	NA
Psychiatric conditions	Diagnosis from NPR, or on medication for neuroleptics, anxiolytics, sedatives or anti-depressants from NPDR	F20-F39	N05A, N05B, N05C, N06A
Cancer	Diagnosis from NPR	C00-C97	NA

64

65

66 **Section S3: Statistical Analysis**
67 Time intervals used in the statistical analysis for each COVID-19 outcome
68 We applied different time intervals for different outcomes due to number of cases. Shorter intervals were applied for
69 infection and hospitalization, while longer intervals were applied for ICU admission and death (see below). An
70 incomplete interval (e.g., 1-6 days for weekly interval) was allowed for the final time interval in a sequence.

COVID-19 outcomes	Time intervals	Week no.
Infection and hospitalization	Weekly	Week 1, 2, 3,4
	Two weeks interval	Week 5-6, 7-8, 9-10
	Three weeks interval	Week 11-13
	Four weeks interval	Week 14-17, 18-21, ..., 54-57
ICU admission and death	Weekly	Week 1,2,3
	Two weeks interval	Week 4-5
	Four weeks interval	Week 6-9, 10-13
	Eight weeks interval	Week 14-21, 22-29, ..., 46-53, 54-57

71
72 Modelling steps in 10% random samples
73 In the Cox model, each individual's follow-up time was first divided according to vaccination status (unvaccinated,
74 first dose and second dose) and then the vaccination exposure periods further divided into time intervals after each
75 dose, until transition to the next dose. For instance, one individual can be divided into 23 records supposing they had
76 first dose on December 1, 2020, and had second dose after four weeks and remained in second dose to the end of
77 follow-up (i.e., 1 record for unvaccinated, 4 records for first dose, and 18 records for second dose), such fine
78 division of follow-up time is computationally challenging. Therefore, we performed two pre-analyses in 10%
79 randomly selected individuals to decide the final model used in the full-scale analyses.
80 One analysis aimed to confirm if the analysis performed in dose 1 and dose 2 separately can yield similar results to
81 an analysis including both doses simultaneously with an interaction term between dose and time interval (dose ×
82 interval). The analysis was performed for COVID-19 infection, and similar results were obtained (Table S1).
83 Other analyses aimed to select appropriate covariates for confounding adjustments, based on change in effect
84 estimate criteria. A list of potential confounders and/or risk factors for COVID-19 were selected based on previous
85 publications, including age, sex, ethnicity, birth country, socioeconomic status, geographic location, cardiovascular
86 diseases, respiratory diseases, kidney function, autoimmune diseases, psychiatric conditions, dementia, cancer, etc.
87 Age and sex were predetermined and always included in the model. Then the other potential confounders and/or risk
88 factors were further included in the model. Inclusion of the covariates that changed effect estimates by >5% were
89 remained in the model. Though ethnicity and geographic location were showed to be important confounders in other
90 studies, they did not meet the criteria of covariates selection (change estimates by >5%), thus were not considered in
91 the final model. Table S2 showed the difference in HRs from different models and fully adjusted model was used in
92 the full-scale analyses.
93

Table S1. Analysis performed in dose 1 and dose 2 separately and analysis including two doses simultaneously with an interaction term between dose and time interval. Analyses were performed for COVID-19 infection in 10% randomly selected individuals.

125

- a) The analysis of VE during Omicron period was modelled the entire follow-up period but only events after December 1, 2021, were considered as incident cases for estimation, and individuals with events before that were censored at their event.

127

falls <50% within 9 months

128

Figure S1. Trend of COVID-19 infection (a) and hospitalization (b) from January 1, 2020 to January 31, 2022

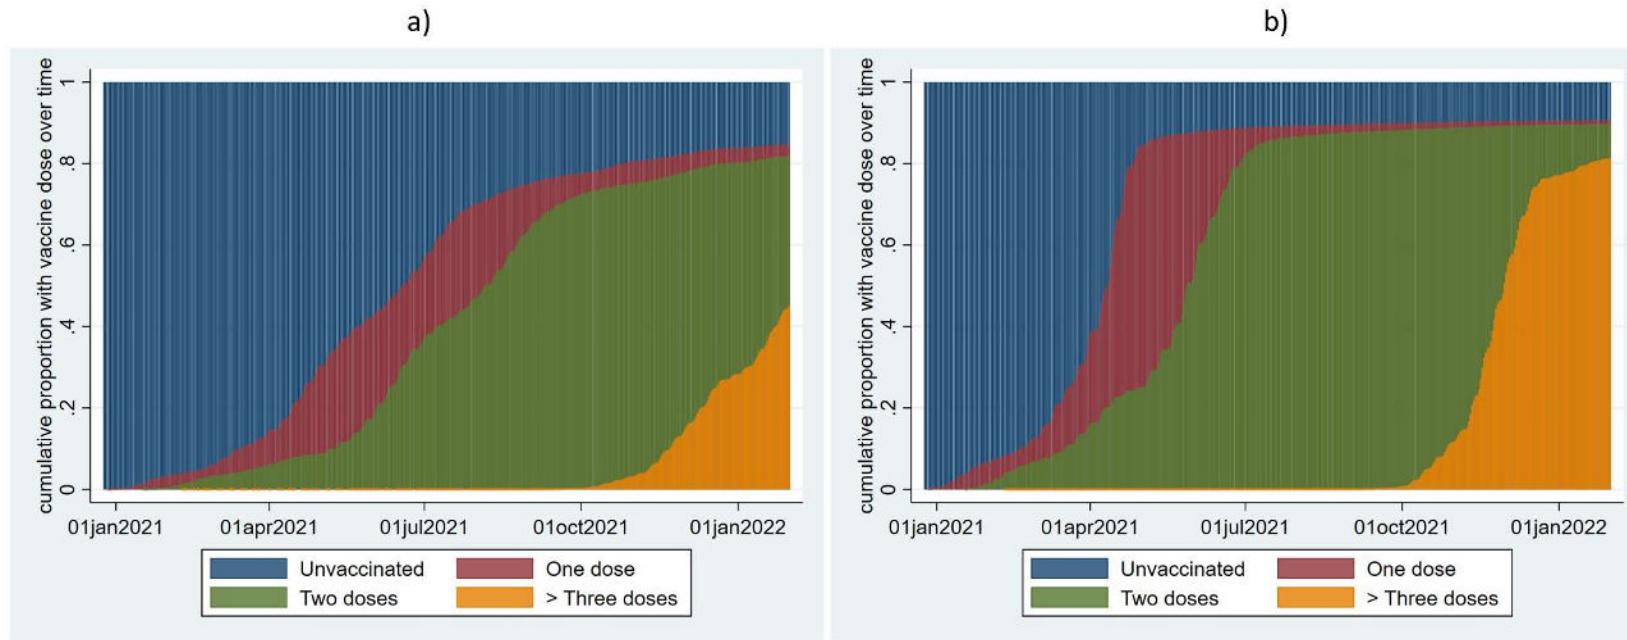

129

130 Figure legend: 7-day moving average of cases of COVID-19 infection (a) and hospitalization (b) during the follow-up. Red lines indicate December 21, 2021, the
131 start date of Omicron period used in the study. There was an obvious increase in infection cases after December 21, 2021.

132

133

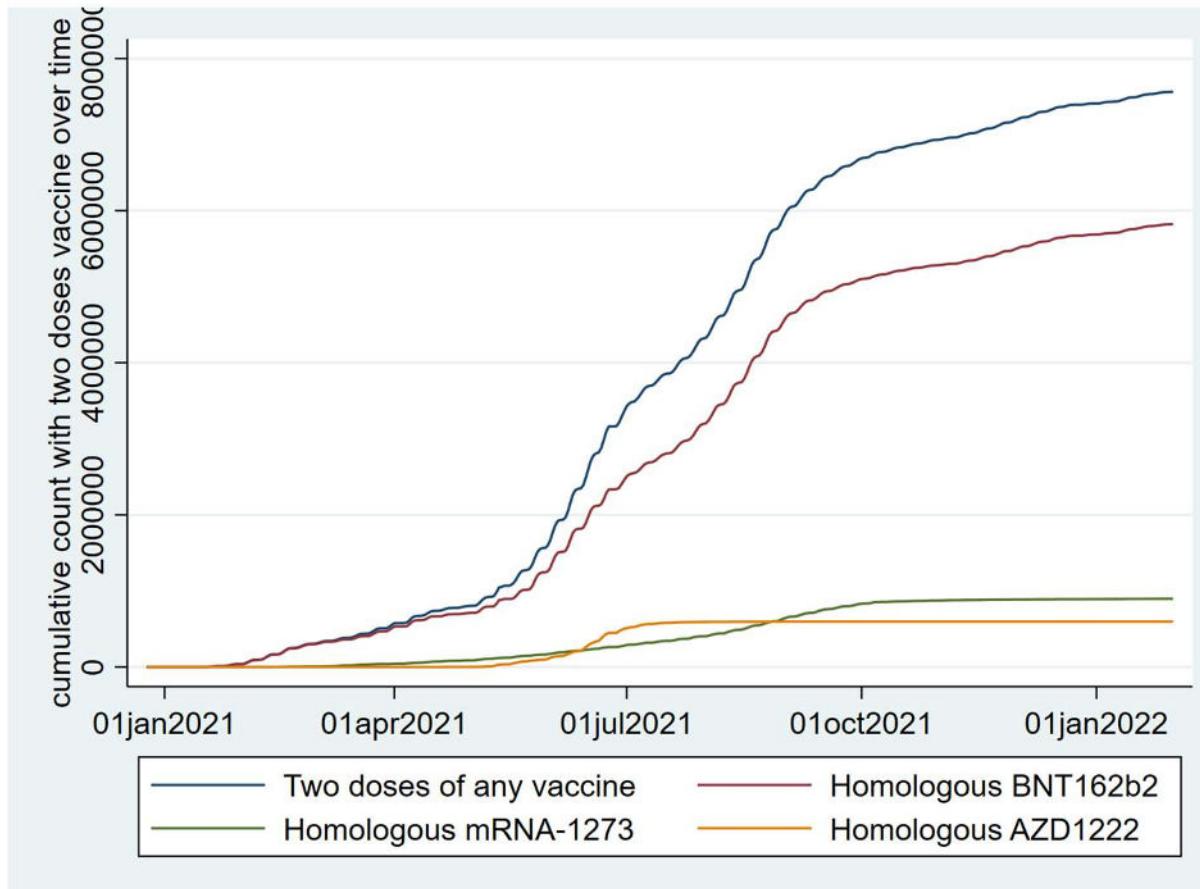

Figure S2. Cumulative proportion of vaccine uptake over time among whole Swedish population (a) and 65+ (b)

134

135

136 **Figure S3. Cumulative count of homologous vaccine type over time**

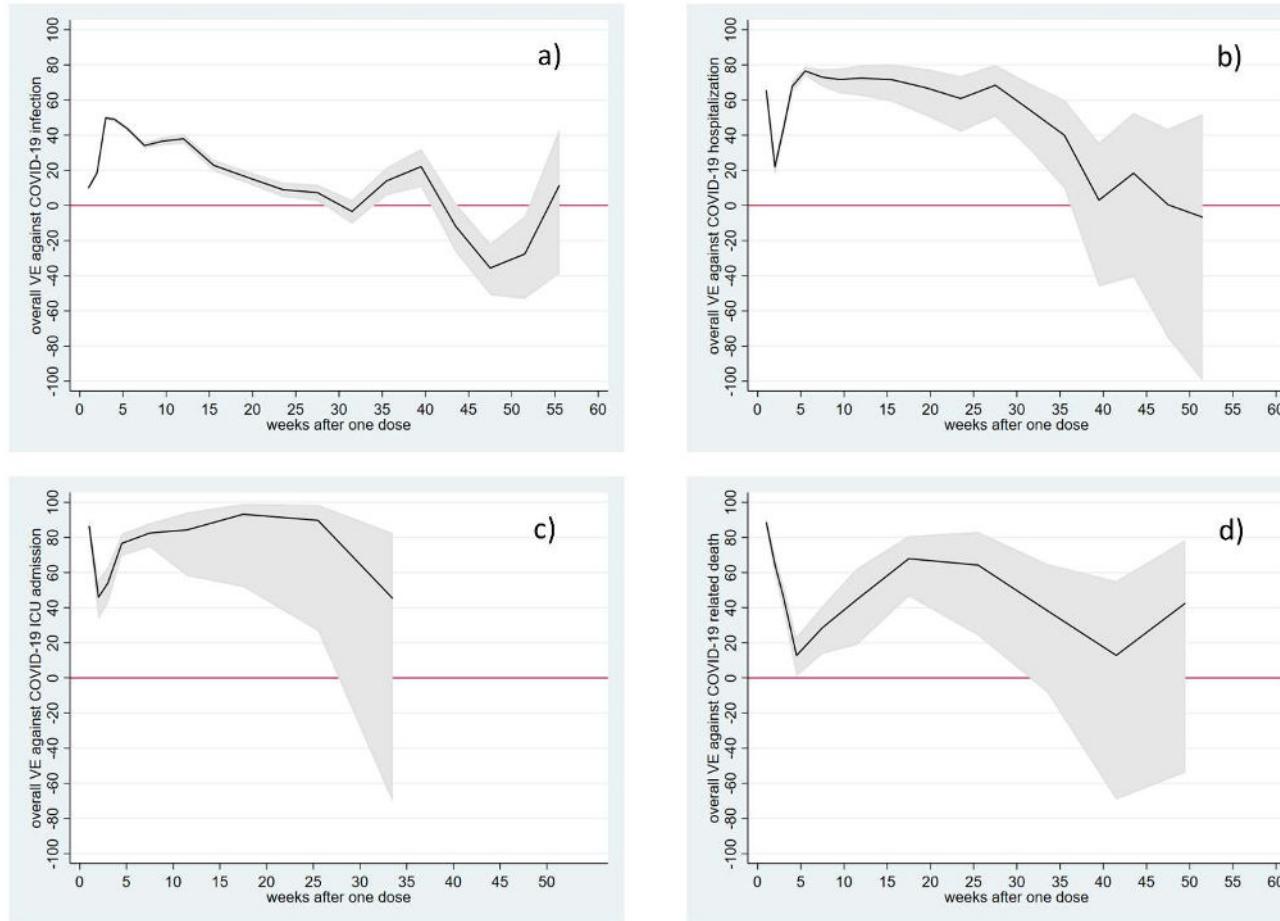

137

138 Figure legend: BNT162b2 is the dominate vaccine brand used in Sweden. AZD1222 was stopped from July 2021.
